

CPSC 367: Cryptography and Security

Michael J. Fischer

Lecture 1

January 15, 2019

Slide credits: Mariana Raykova, Tom Ristenpart, Stefano Tessaro, as well as the teaching slides for *Introduction to Security* by Goodrich, Tamassia

Highlights from Syllabus

Data Breaches

Defending Against Attacks

Highlights from Syllabus

Expectations

Read the syllabus! Some highlights:

- ▶ Pay attention to policies on plagiarism, submitting your work, and electronics in class.
- ▶ Teaching assistant is Jaspal Singh.
- ▶ The midterm is scheduled; the final not yet.
- ▶ You will use the Zoo for programming and Canvas for homework submissions.
- ▶ Do problem set 1!

Class attendance

Class attendance and class participation are required. **Why?**

- ▶ I say things that don't find their way into the lecture notes.
- ▶ Your questions help me pace my lectures and address the needs of the class.
- ▶ I like teaching much better than lecturing to an empty room.
- ▶ If you're confused, others are likely confused too and might be brave enough to ask for clarification. You can learn from them.

Please always feel free to ask questions.

Also, please let me know in case you have to miss class.

Electronics during class

You may use laptops, smart phones, and other electronic devices *for purposes related to the lecture only.*

Permitted:

- ▶ Taking notes.
- ▶ Looking briefly at lecture-related materials on the web.

Not permitted:

- ▶ Reading email.
- ▶ Visiting Facebook, Twitter, and other social media sites.
- ▶ Texting/messaging your friends.

If you must answer a call or engage in a not-permitted activity, please step out of the room so as to not disrupt class.

Data Breaches

Protecting information in the real world

Massive security breaches are disclosed almost daily.

- ▶ Identity theft.
- ▶ Industrial espionage.
- ▶ Cyberwarfare.
- ▶ Denial-of-service.
- ▶ Surveillance.
- ▶ Misuse of personal data.

Apple vs. FBI is over, but the encryption battle rages on

Encryption is once again the bogeyman after this week's attacks in Belgium, and the lessons of the FBI's abandoned case against Apple could be lost

1

InfoWorld | Mar 25, 2016

The abrupt end to the FBI's legal battle with Apple this week resolved none of the underlying

Even the NSA can't protect its secrets

Edward Snowden: Leaks that exposed US spy programme

17 January 2014 | [US & Canada](#)

Edward Snowden, a former contractor for the CIA, left the US in late May after leaking to the media details of extensive internet and phone surveillance by American intelligence. Mr Snowden, who has been granted temporary asylum in Russia, faces espionage charges over his actions.

As the scandal widens, BBC News looks at the leaks that brought US spying activities to light.

US spy agency 'collects phone records'

The **scandal broke in early June 2013** when the Guardian newspaper reported that the US National Security Agency (NSA) was collecting the telephone records of tens of millions of Americans.

Security software bugs can be exploited

The Heartbleed Bug

The Heartbleed Bug is a serious vulnerability in the popular OpenSSL cryptographic software library. This weakness allows stealing the information protected, under normal conditions, by the SSL/TLS encryption used to secure the Internet. SSL/TLS provides communication security and privacy over the Internet for applications such as web, email, instant messaging (IM) and some virtual private networks (VPNs).

The Heartbleed bug allows anyone on the Internet to read the memory of the systems protected by the vulnerable versions of the OpenSSL software. This compromises the secret keys used to identify the service providers and to encrypt the traffic, the names and passwords of the users and the actual content. This allows attackers to eavesdrop on communications, steal data directly from the services and users and to impersonate services and users.

Network configuration errors

Pakistan hijacks YouTube

Late in the (UTC) day on 24 February 2008, Pakistan Telecom (AS 17557) began advertising a small part of YouTube's (AS 36561) assigned network. This story is almost as old as BGP. Old hands will recognize this as, fundamentally, the same problem as the [infamous AS 7007 from 1997](#), a [more recent ConEd mistake of early 2006](#) and even [TTNet's Christmas Eve gift 2004](#).

Just before 18:48 UTC, Pakistan Telecom, in response to [government order](#) to block access to YouTube (see [news item](#)) started advertising a route for 208.65.153.0/24 to its provider, PCCW (AS 3491). For those unfamiliar with BGP, this is a more specific route than the ones used by YouTube (208.65.152.0/22), and therefore most routers would choose to send traffic to Pakistan Telecom for this slice of YouTube's network.

I became interested in this immediately as I was concerned that I wouldn't be able to spend my evening watching imbecilic videos of cats doing foolish things (even for a cat). Then, I started to examine our mountains of BGP data and quickly noticed that the correct AS path ("Will the real YouTube please stand up?") was getting restored to most of our peers.

Personal info can be compromised despite anonymization

Researchers reverse Netflix anonymization

Robert Lemos, SecurityFocus 2007-12-04

In a dramatic demonstration of the privacy dangers of databases that collect consumer habits, two researchers from the University of Texas at Austin have shown that a handful of movie ratings can identify a person as easily as a Social Security number.

The researchers -- graduate student Arvind Narayanan and professor Vitaly Shmatikov, both from the Department of Computer Sciences at the University of Texas at Austin -- claim to have identified two people out of the nearly half million anonymized users whose movie ratings were released by online rental company Netflix last year. The company published the large database as part of its \$1 million Netflix Prize, a challenge to the world's researchers to improve the rental firm's movie-recommendation engine.

"Releasing the data and just removing the names does nothing for privacy," Shmatikov told SecurityFocus. "If you know their name and a few records, then you can identify that person in the other (private) database."

"Releasing the data and just removing the names does nothing for privacy. If you know their name and a few records, then you can identify that person in the other (private) database."

Vitaly Shmatikov, Professor of Computer Science,
University of Texas at Austin

While Netflix's dataset did not include names, instead using an anonymous identifier for each user, the collection of movie ratings -- combined with a public database of ratings -- is enough to identify the people, the researchers argued in a [paper](#) published soon after Netflix released the data, but which only recently came to light. Narayanan and Shmatikov demonstrated the danger by using public reviews published by a "few dozen" people in the Internet Movie Database (IMDb) to identify movie ratings of two of the users in Netflix's data.

Exposing movie ratings that the reviewer thought were private could expose significant details about the person. For example, the researchers found that one of the people had strong -- ostensibly private -- opinions about some liberal and gay-themed films and also had ratings for some religious films.

More generally, the research demonstrated that information that a person believes to be benign could be used to identify them in other private databases. In privacy and intelligence circles, the result has been understood for decades, but the University of Texas paper visually demonstrates the dangers, said Bruce Schneier, founder and chief technology officer of managed security provider BT Counterpane.

WannaCry Ransomware¹

Criminals go where the money is, and cybercriminals are no exception.

And right now, the money is in ransomware.

It's a simple scam. Encrypt the victim's hard drive, then extract a fee to decrypt it. The scammers can't charge too much, because they want the victim to pay rather than give up on the data. But they can charge individuals a few hundred dollars, and they can charge institutions like hospitals a few thousand. Do it at scale, and it's a profitable business.

¹Notes by Bruce Schneier, *Crypto-Gram*, June 15, 2017.

WannaCry Ransomware (cont.)

And scale is how ransomware works. Computers are infected automatically, with viruses that spread over the internet. Payment is no more difficult than buying something online – and payable in untraceable bitcoin – with some ransomware makers offering tech support to those unsure of how to buy or transfer bitcoin. Customer service is important; people need to know they'll get their files back once they pay.

And they want you to pay. If they're lucky, they've encrypted your irreplaceable family photos, or the documents of a project you've been working on for weeks. Or maybe your company's accounts receivable files or your hospital's patient records. The more you need what they've stolen, the better.

The particular ransomware making headlines is called WannaCry, and it's infected some pretty serious organizations.

Defending Against Attacks

The Digital Landscape

Computer Security

How is security achieved in the real world?

- ▶ **Prevention:** Physical barriers, access controls, encryption, firewalls, human awareness, etc.
- ▶ **Detection:** Audits, checks and balances.
- ▶ **Legal means:** Laws, patents, trademarks, copyrights, sanctions against wrongdoers.
- ▶ **Concealment:** Camouflage, steganography.

Different stakeholders have differing interests

Consider an on-line banking web site.

- ▶ What are the interests of the customer?
- ▶ What are the interests of the bank?
- ▶ What are the interests of possible intruders?
- ▶ Can the bank trust the customer? Why or why not?
- ▶ Can the customer trust the bank? Why or why not?
