

Sean Haufler

CSPC 457

10/17/13

# Background

- Designed & implemented for US Navy
- Created to protect gov't communication
- 80% of Tor's ~\$2M funding paid for by US gov't

# Design Goals

- Anonymous
- Low-latency
- Usable
- Flexible
- Simple

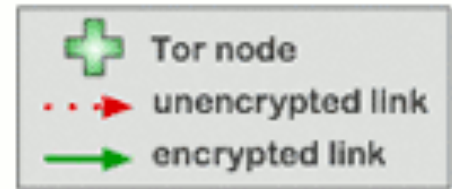

# Implementation

- TCP
- Create circuit via 3 tor nodes
  - Circuit change every ~10min (configurable)
  - No single point of failure
- Data chunked in 512 byte “cells”
  - Inefficient for bandwidth w/ small data transfers
    - E.g. IRC
  - Used to make it harder to guess what type of content is being transferred by packet size

# How Tor Works

## How Tor Works: 1

Alice

Step 1: Alice's Tor client obtains a list of Tor nodes from a directory server.

Dave

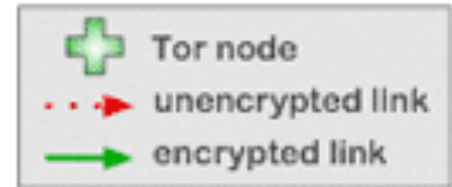

Jane

Bob

# How Tor Works

## How Tor Works: 2

Alice

Step 2: Alice's Tor client picks a random path to destination server. **Green links** are encrypted, **red links** are in the clear.

Dave

Jane

Bob

# How Tor Works

## How Tor Works: 3

Alice

Step 3: If at a later time, the user visits another site, Alice's tor client selects a second random path. Again, **green links** are encrypted, **red links** are in the clear.

# Inside a Circuit

# Limitations

- Doesn't protect:
  - Computer configuration → use Privoxy
  - End-to-end timing attacks
    - Analysis of traffic + timestamp of your client and the destination can pinpoint traffic to you
  - Plugins like Flash can query your local IP
- Also:
  - First server could see who you are
  - 3rd server could see your traffic

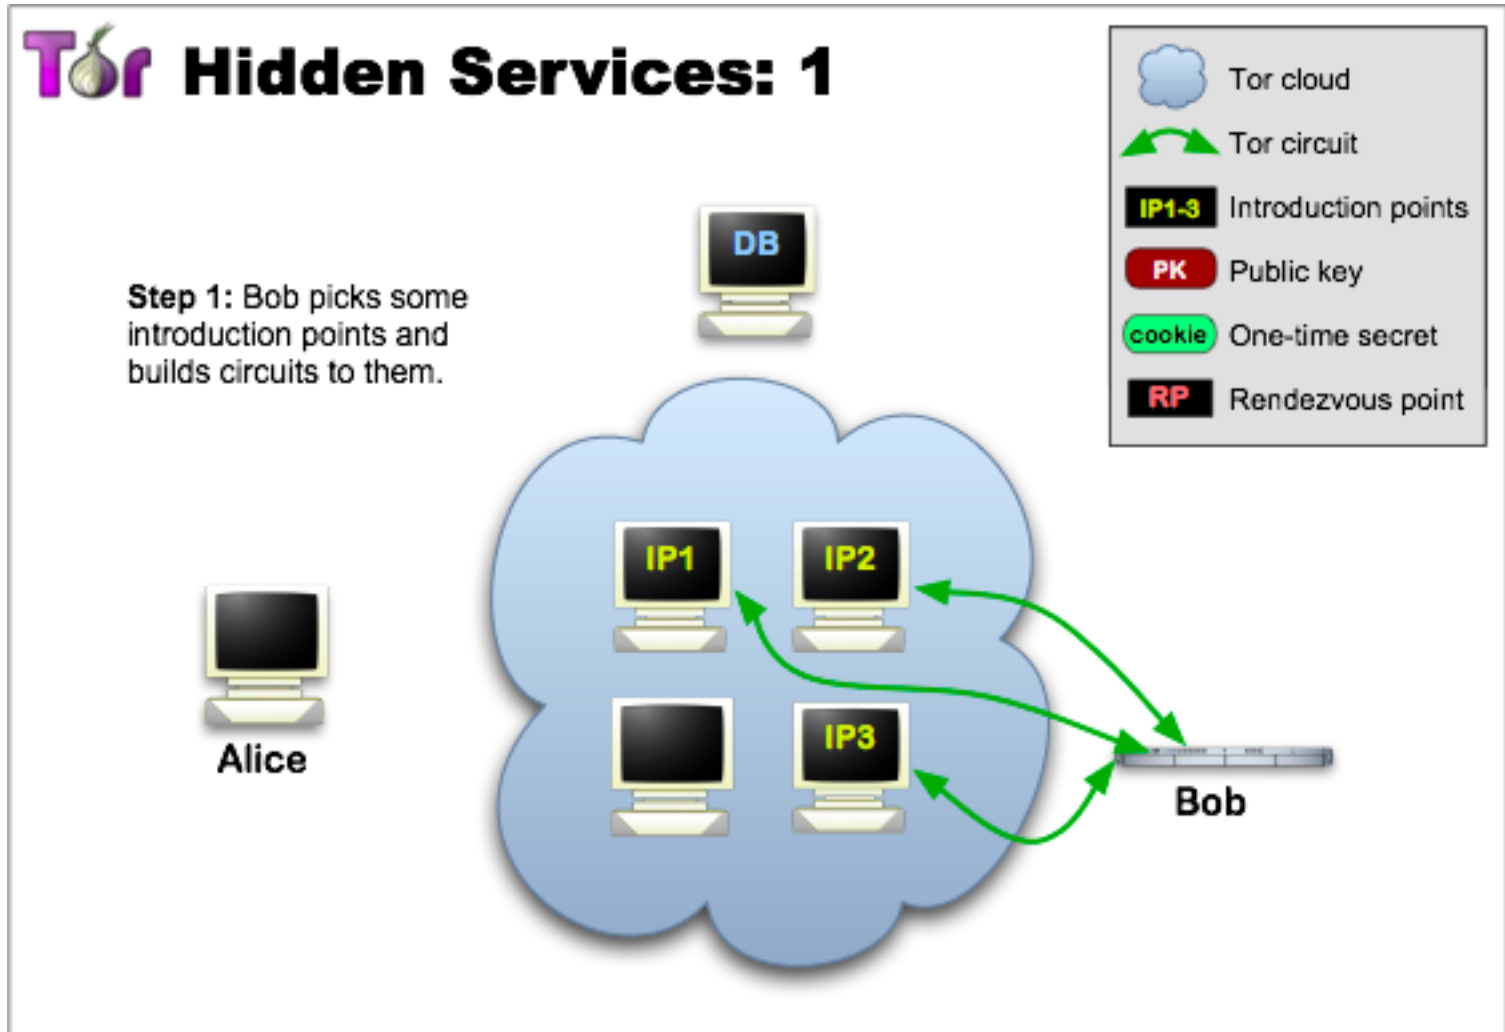

# Limitations

- Tor IPs are public
- Filtering based on the fingerprint of the Tor TLS handshake
  - Several countries have blocked Tor
    - China, Iran, Japan, Russia
    - Intercept connection between client and 1<sup>st</sup> relay
    - Solution: bridge relays!
  - Application developers can block Tor
    - Even in US: Craigslist
    - Application server detects 3<sup>rd</sup> relay's IP

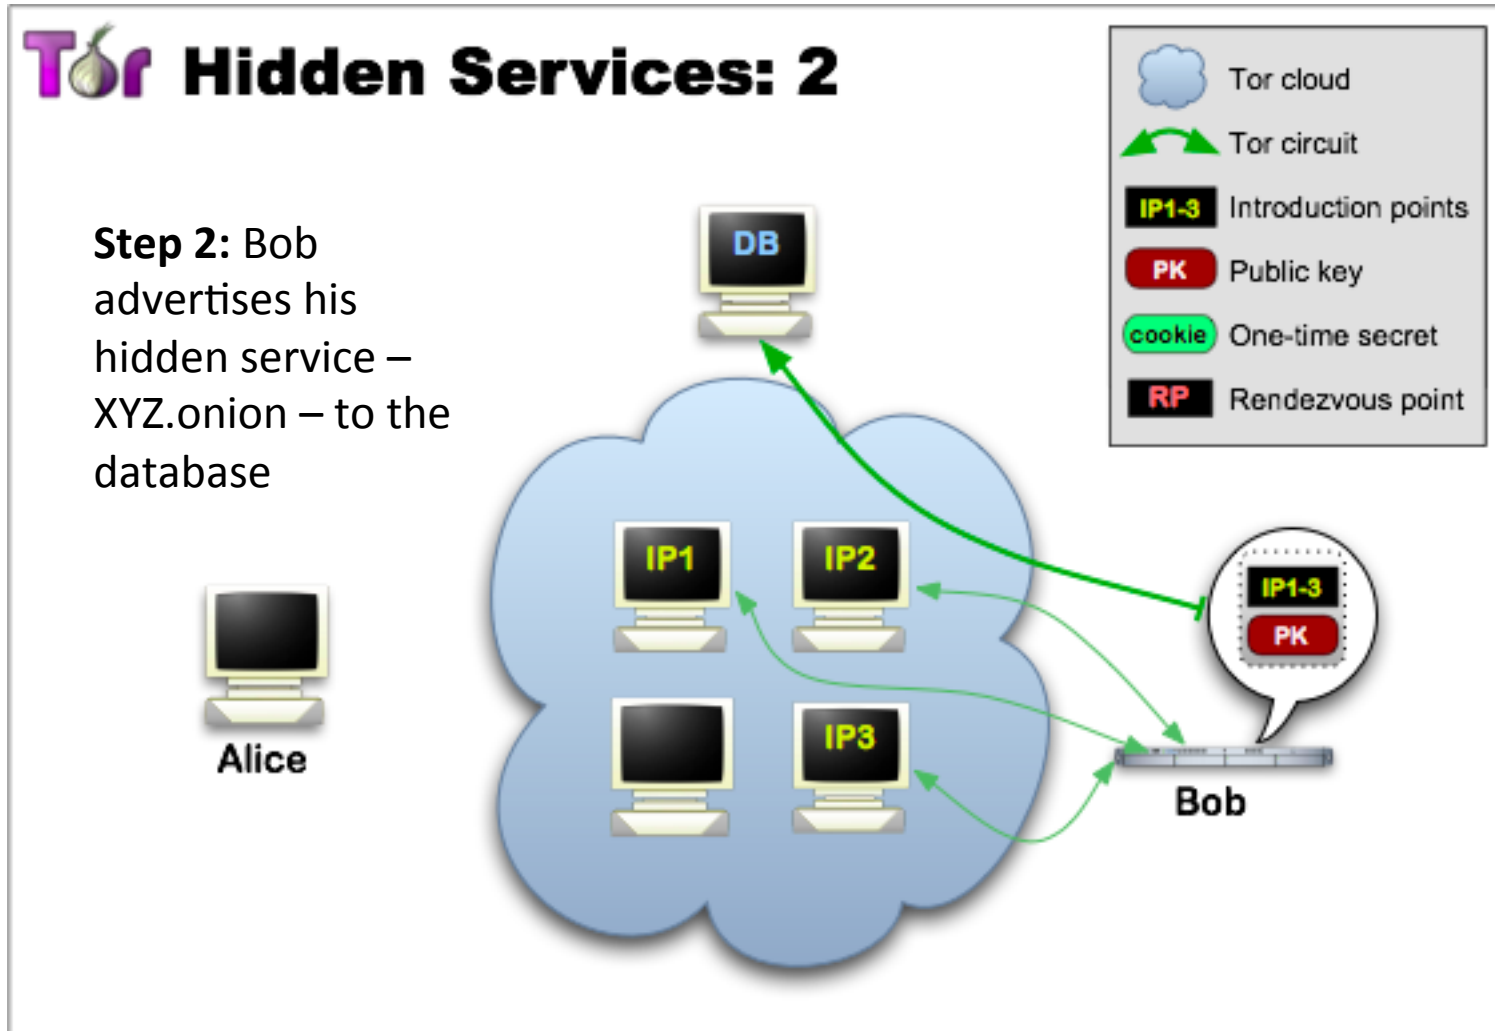

# How to 'Tor Websites' work?

- Tor Hidden Services
- Need to connect a client and server s.t.
  - Client info protected from server, AND
  - Server info protected from client
- How?
  - .onion address
  - 2 circuits
- E.g. Silk Road → <http://6zyze2mkwyla7jwe.onion>

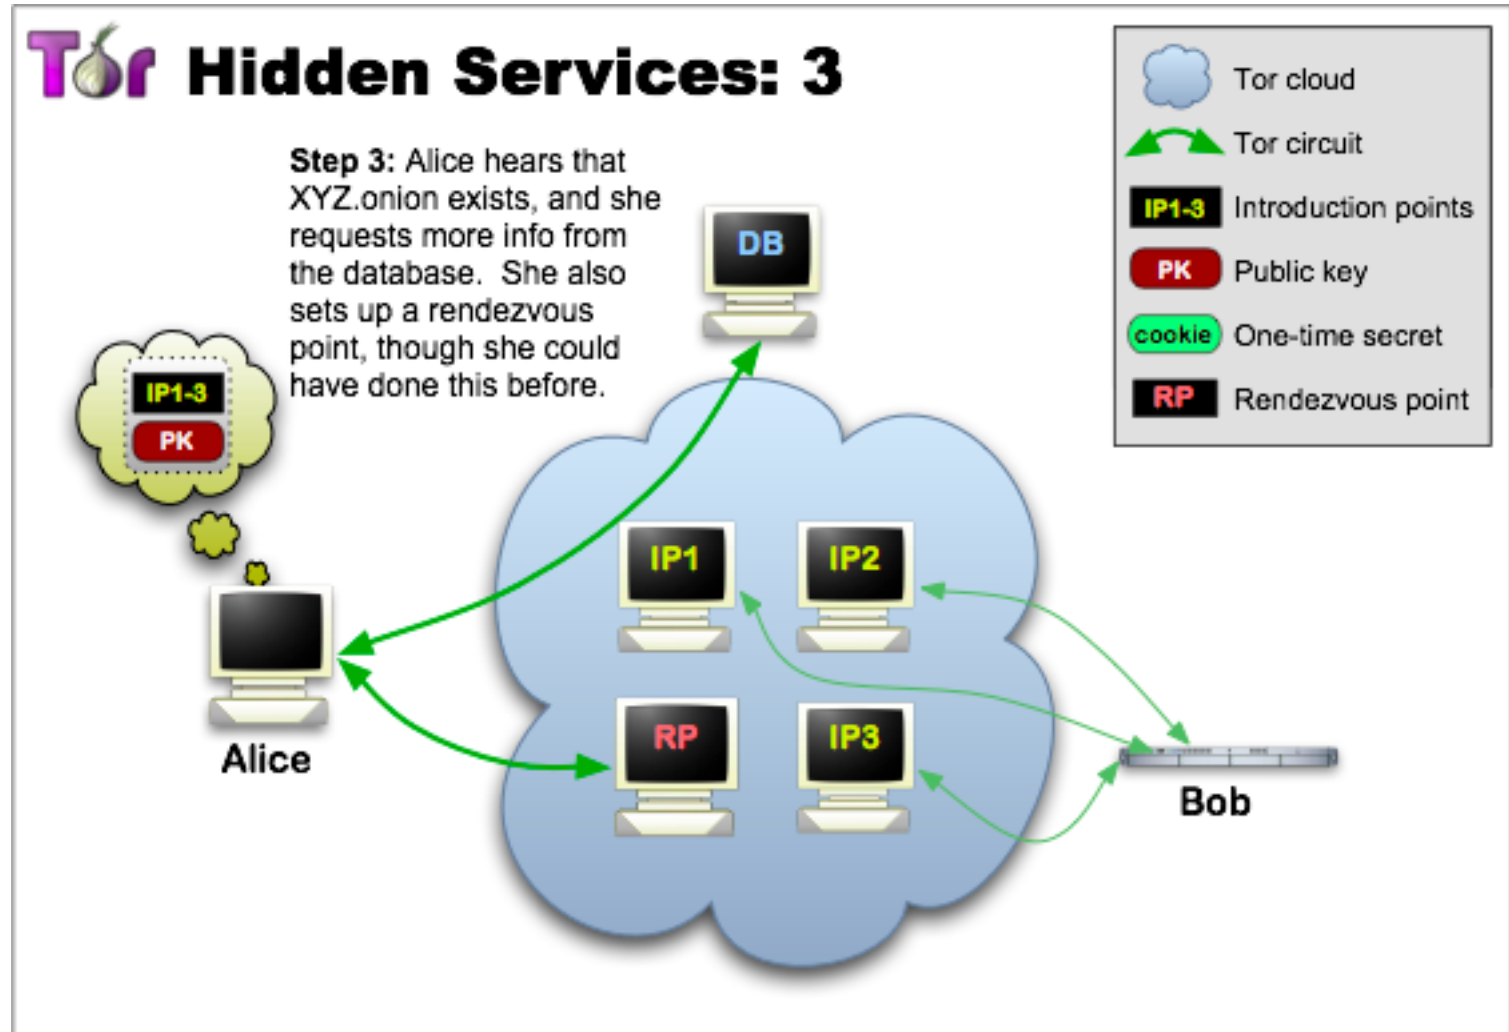

# Hidden Service Protocol

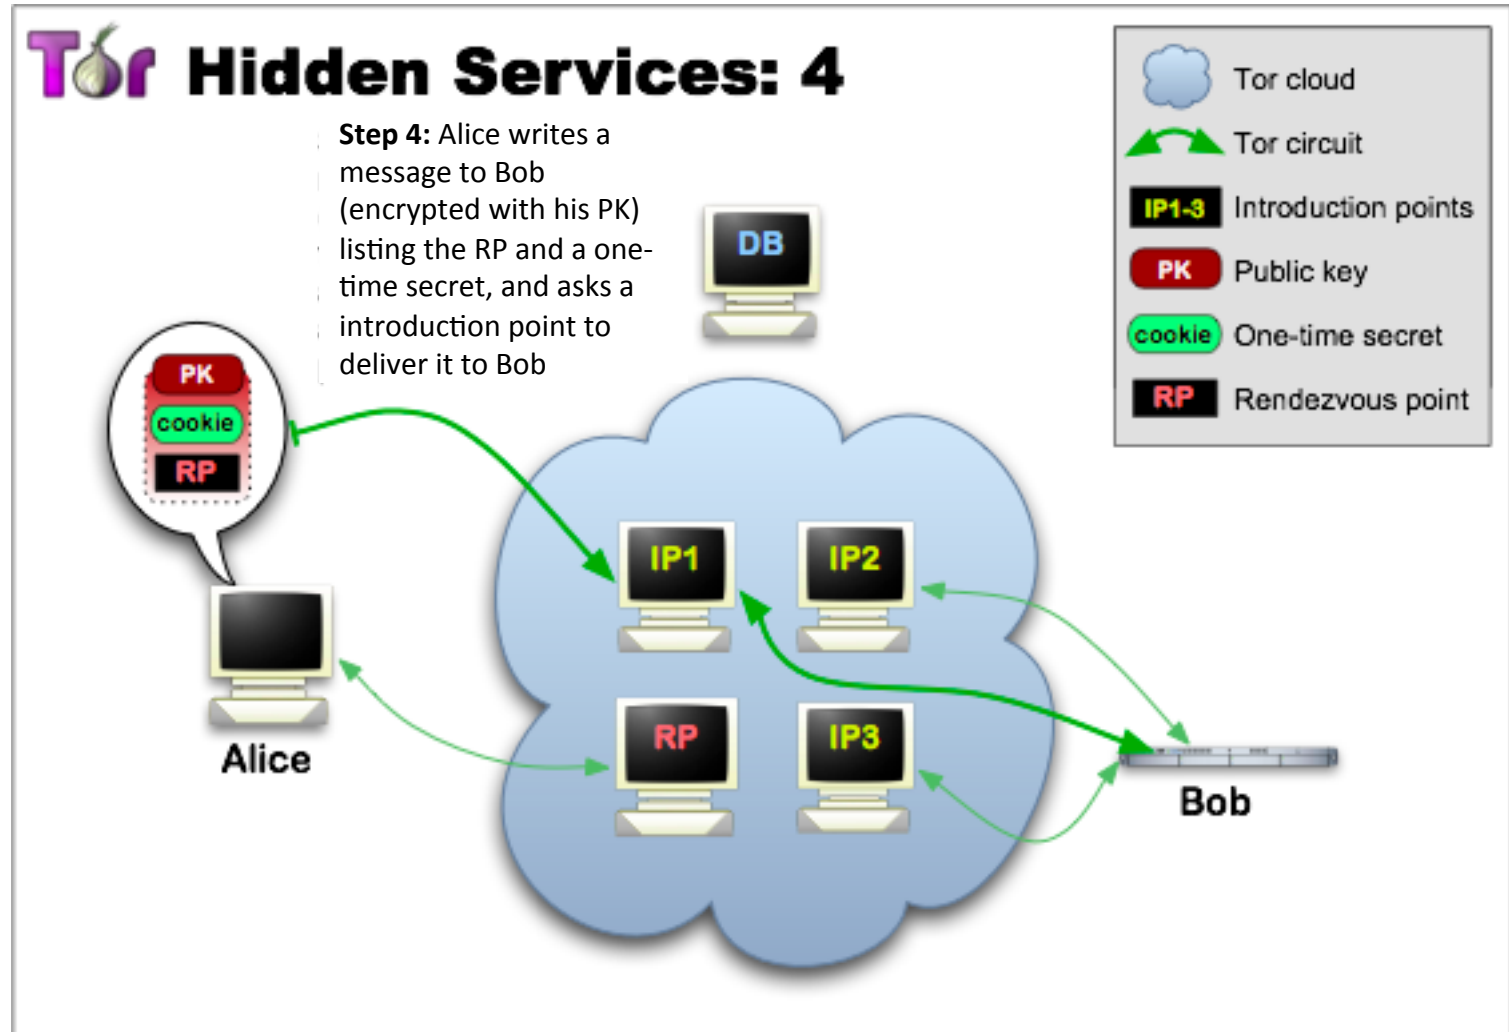

# Hidden Service Protocol

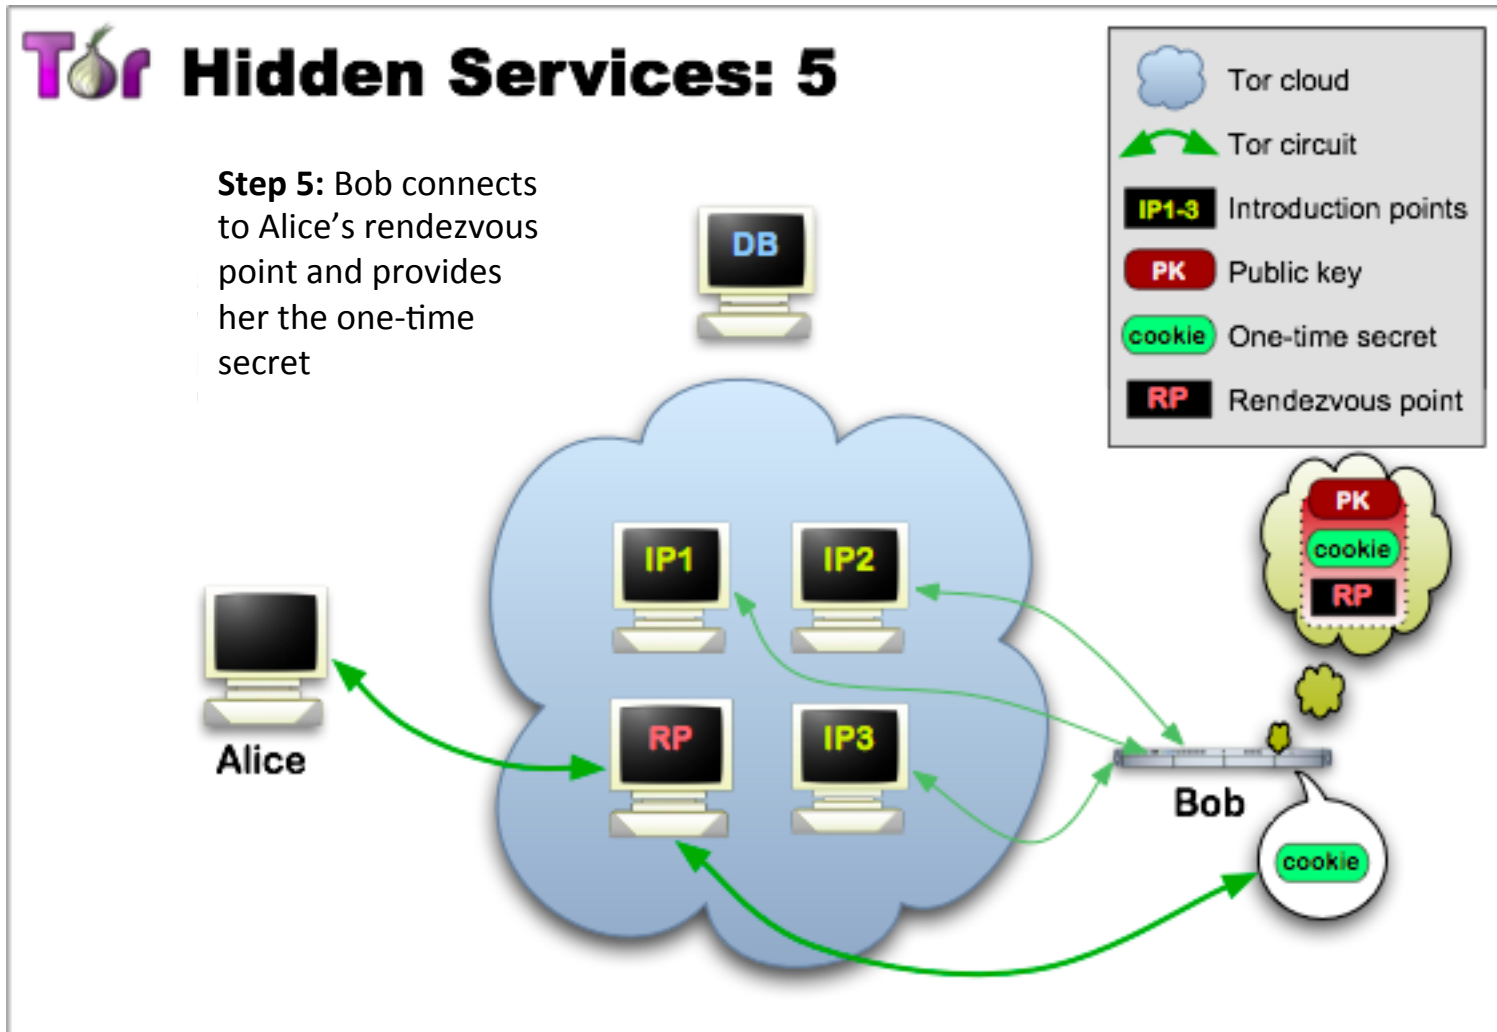

# Hidden Service Protocol

# Hidden Service Protocol

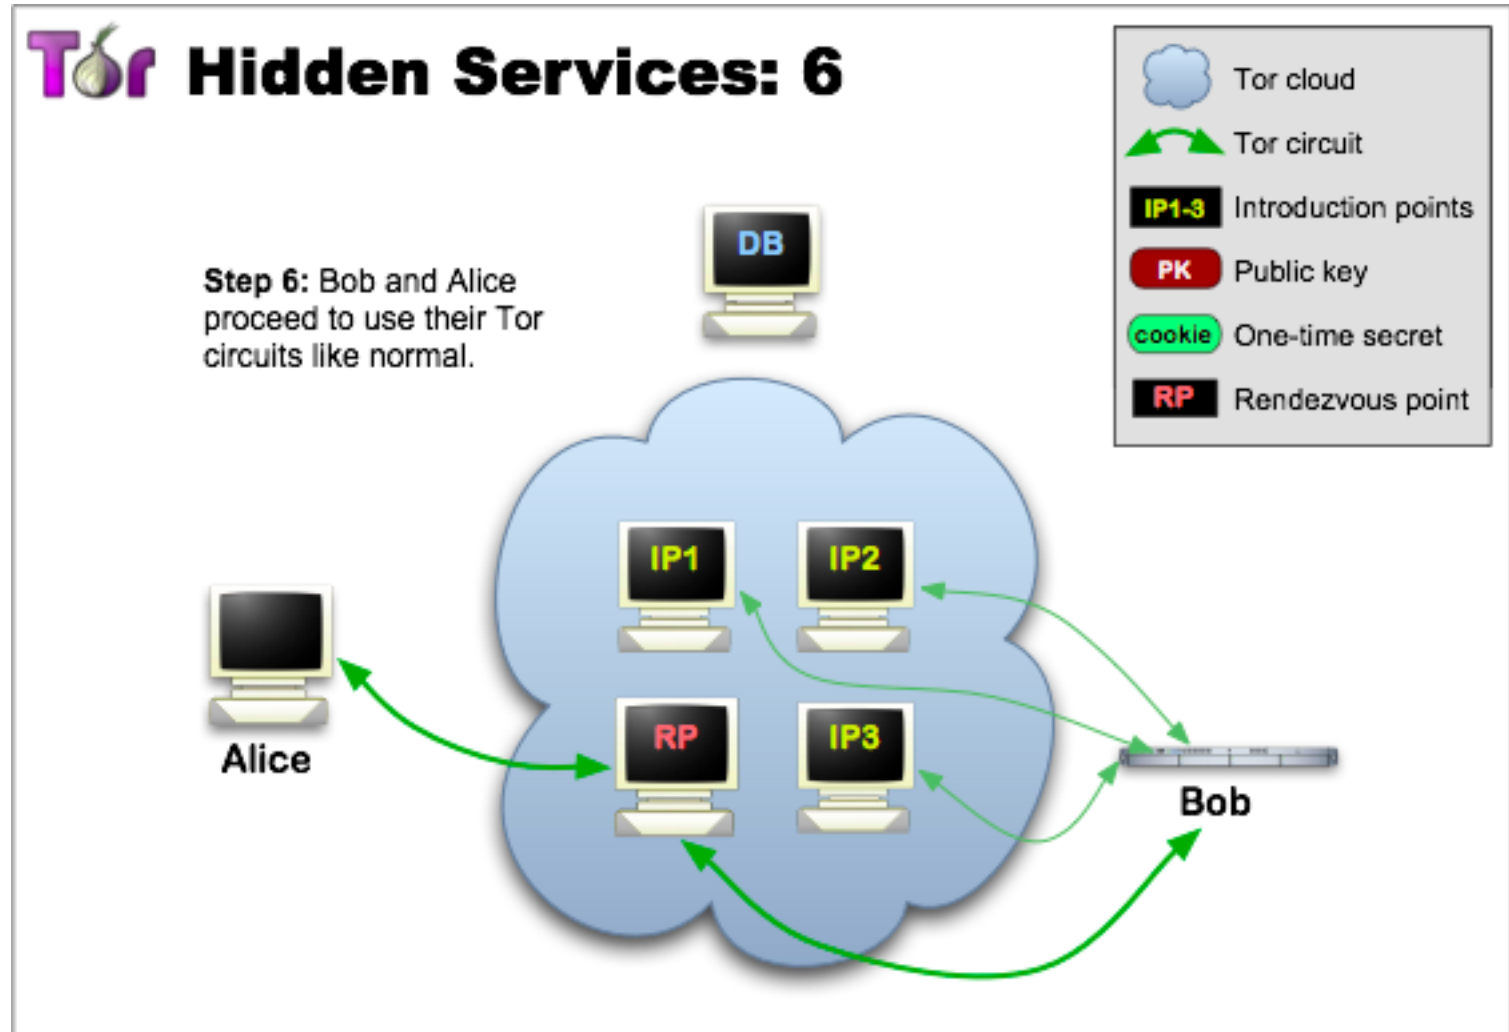

# Hidden Service Protocol

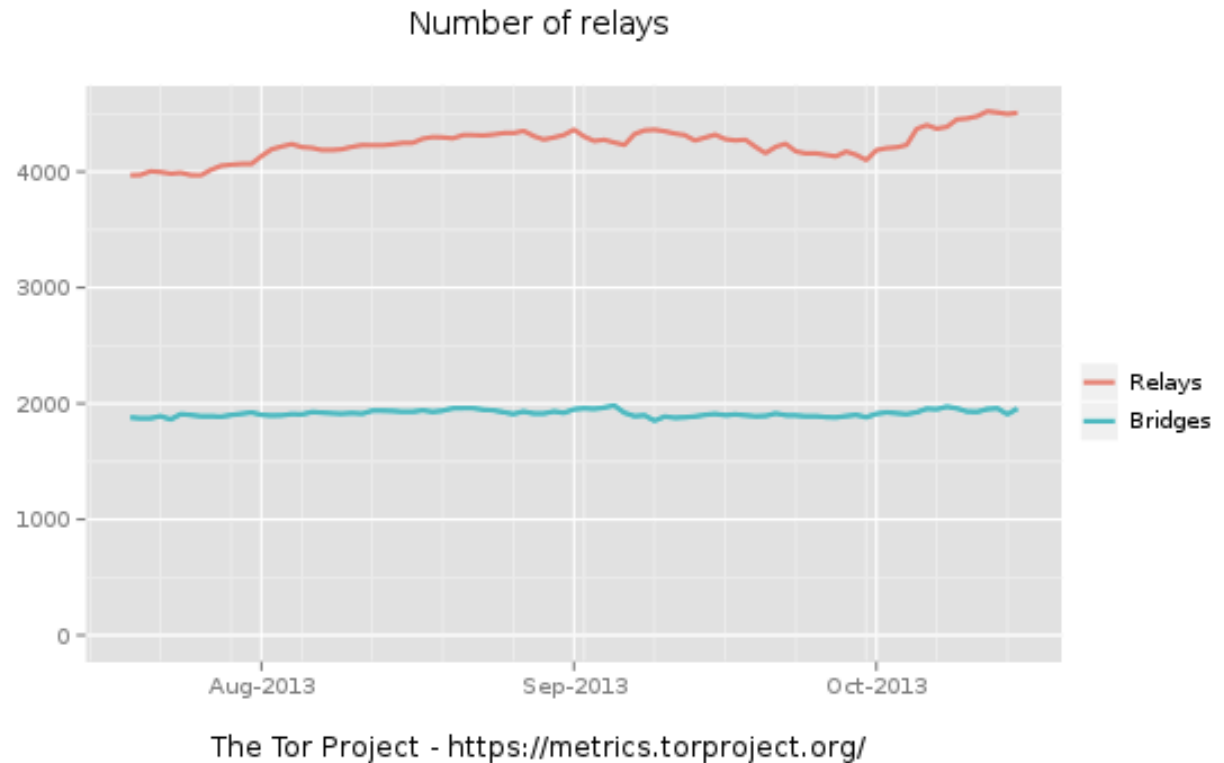

# Hidden Service Protocol

# How widespread is it?

- ~4,000 relays
- ~2,000 bridges (non-public relays)
- ~1 GB/s

# Usage Graph – last 3 months

Directly connecting users from all countries

The Tor Project - <https://metrics.torproject.org/>

# Usage Graph – last 3 years

Directly connecting users from all countries

The Tor Project - <https://metrics.torproject.org/>

# It's not sustainable!

- Tons of clients, very few relays
- How do you incentivize people to be Tor relays?
  - More relays leads to:
    - Faster bandwidth, more throughput
    - Less chance of endpoint hijacking (if the new relays aren't “traitors”)

# Possible Incentives

- Relays get “priority”
- Pay for priority service with bitcoins
  - More incentives to ‘cheat’
  - Behavioral economics: people less likely to ‘volunteer’
- Won’t be implemented anytime soon

# Open Qs

- Should the circuit/path length be extended to improve security?
- Should Tor un-publicize relay IPs so they don't get blocked at the application layer?
- Should Tor make every node a relay?
