

Blocco

10 units  
4 battlefields

$$\begin{array}{l} (10, 0, 0, 0) \\ (9, 1, 0, 0) \\ (\textcolor{green}{7}, 0, 1, 0) \\ (\textcolor{purple}{9}, 0, 0, 1) \\ \vdots \\ (0, 0, 0, 10) \end{array}$$

$$\# \text{ of pure strategies} = \binom{13}{10}$$

286

string of 10 0's

3 1's

choose 10 locations of 0's  
out of 13 locations

538: 100 units

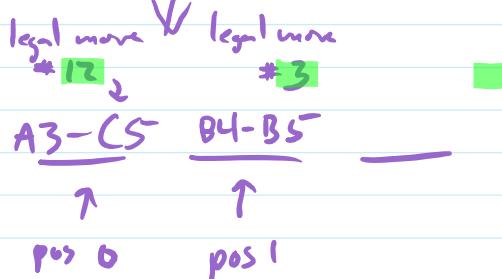

10 battle fields

$$\binom{100}{100} \approx 4 \text{ trillion}$$

Chess as a simultaneous game

chess strategy = function from chess positions to moves

- 1) P1, P2 simultaneously choose strat
- 2) play game accordingly

$$\frac{\text{A8-H1}}{\text{pos } 10^{40}}$$

assume ~30 legal moves per pos

assume ~30 legal moves per pos

~  $30^{(10^{40})}$  different strategies

## Sizes of Games

Minimax( $pos$ )

$b = \text{branching factor}$  If  $pos$  is terminal, return value determined by rules  
 $= \text{avg moves possible}$  game over  
 $\hookrightarrow$  check who won +1: P1  
 $0: \text{draw}$   
 $-1: P2$

$d = \text{depth}$   
 $= \text{avg length}$   
 $\# \text{pos} \approx b^d$

Else if  $pos$  is P1's turn then return  $\max_{\text{pos} \rightarrow \text{pos}'} \text{MM}(\text{pos}')$   
Else return  $\min_{\text{pos} \rightarrow \text{pos}'} \text{MM}(\text{pos}')$

Tic-Tac-Toe

very rough est of # pos  
 $\leq 3^9 \approx 20000$

Mancala

$\leq \binom{49}{36} \approx 262 \text{ billion}$

2-player Yahtzee

$\leq 4 \cdot 10^{18}$

Checkers

$\leq 10^{20}$

Chess

$\leq 10^{43}$

Go

$\leq 10^{172}$

What to do with games of high complexity?

heuristics - estimate of position value

Ex : checkers % of remaining pieces that are black 0.8  
(scaled to (-1, 1)) 0.4  
heuristic =  $\frac{1}{2}$

chess assign value to each type of piece pawn = 1  
knight, Bishop = 3  
% of value of remaining pieces belonging to white (scaled) rook = 5  
queen = 9

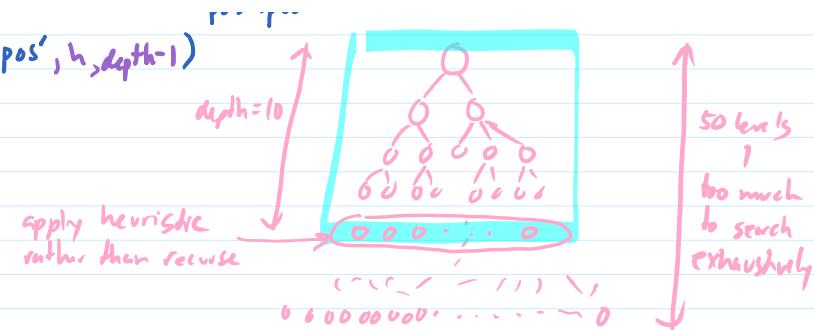

Minimax( $pos, h, \underline{\text{depth}}$ )  $\rightarrow$  depth bound; higher bounds yield results closer to unbounded MM  
If  $pos$  is terminal, return  $\text{value}(pos)$

If  $\text{depth} = 0$ , return  $h(pos)$

Else if  $pos$  is P1's turn then return  $\max_{\text{pos} \rightarrow \text{pos}'} \text{MM}(\text{pos}', h, \text{depth}-1)$

Else return  $\min_{\text{pos} \rightarrow \text{pos}'} \text{MM}(\text{pos}', h, \text{depth}-1)$

Else return  $\min_{pos \rightarrow pos'} MM(pos', h, depth-1)$

$Negamax(pos, h, depth, sign)$

If  $pos$  is terminal, return  $value(pos) \cdot sign$

If  $depth = 0$ , return  $h(pos) \cdot sign$

Else return  $\max_{pos \rightarrow pos'} -MM(pos', h, depth-1, -sign)$

Iterative Deepening - to get value from MM in set time w/ depth high

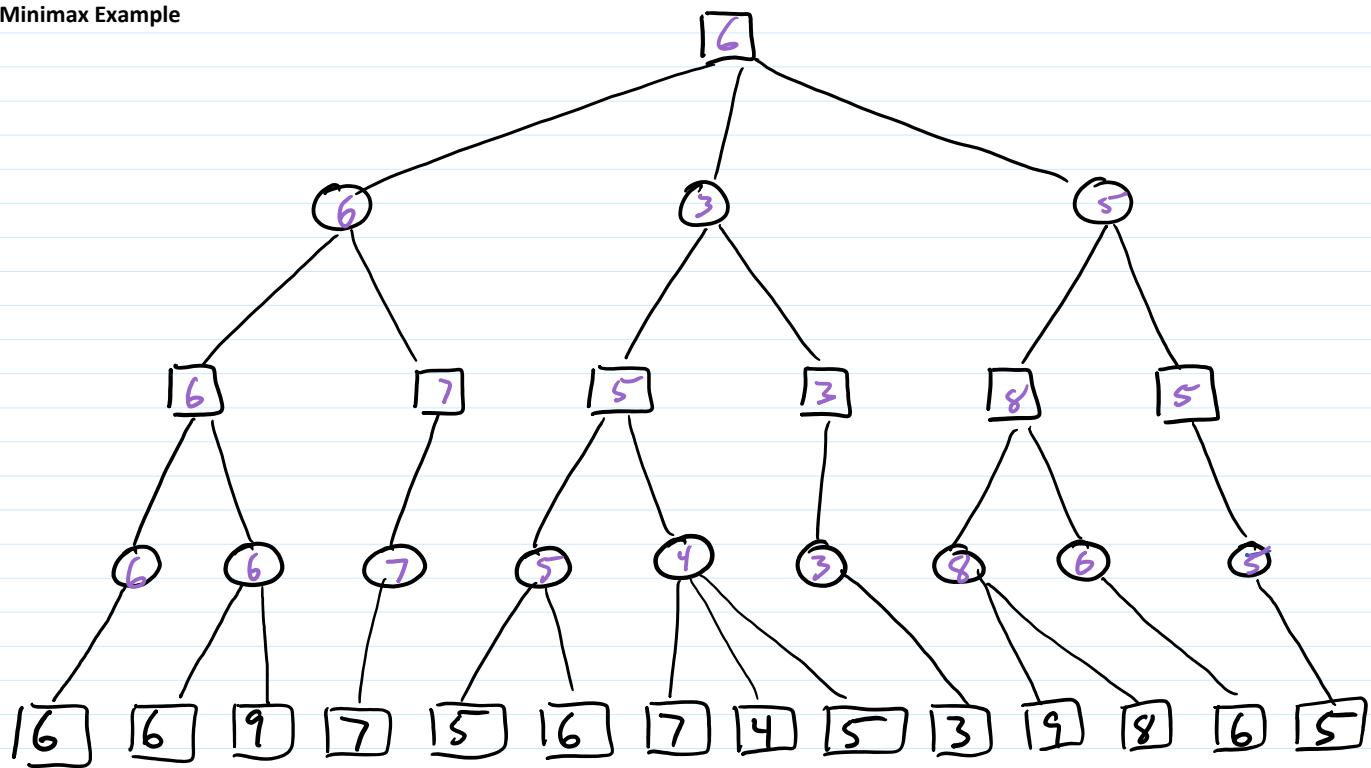

$depth \leftarrow 2$   
while not out of time  
do  $MM(pos, h, depth)$   
 $depth \leftarrow depth + 1$

return values, best move returned by last call to MM that finished

Further ideas - search deeper in promising branches (those that seem like good moves)

shallower on bad branches

### Minimax Example

Modified example from [http://en.wikipedia.org/wiki/AlphaBeta\\_pruning](http://en.wikipedia.org/wiki/AlphaBeta_pruning)
