

AlphaBeta wants to know is next child better than best so far?

- (for max node)
- possible answers:
- 1) no value = α
 - 2) yes, and the value is exactly $\alpha < \text{value} < \beta$
 - 3) yes, and so good you don't even want to know value $\geq \beta$

Scout wants to know is next child better than best so far?

- (for max node)
- possible answers:
- 1) no value = α
 - 2) yes value $> \alpha$ ← if yes, need to distinguish between

Scout ($p, \alpha, \beta, \text{depth}, h$)

if p is terminal then return $\text{value}(p)$

if $\text{depth} = 0$ then return heuristic(p)

if p is a max position

best $\leftarrow -\infty$

for each reachable position p' and while $\alpha < \beta$

if p' is first pos

score $\leftarrow \text{Scout}(p', \alpha, \beta, \text{depth}-1, h)$

else

score $\leftarrow \text{AB}(p', \alpha, \alpha+1, \text{depth}-1, h)$

if $\alpha < \text{score} < \beta$

score $\leftarrow \text{Scout}(p', \text{score}, \beta, \text{depth}-1, h)$

best $\leftarrow \max(\text{best}, \text{score})$

$\alpha \leftarrow \max(\text{best}, \alpha)$

return best

(or fail-hard version)

else

⋮ min position; symmetric

already passing null window, so no reason for Scout

in order of \downarrow goodness

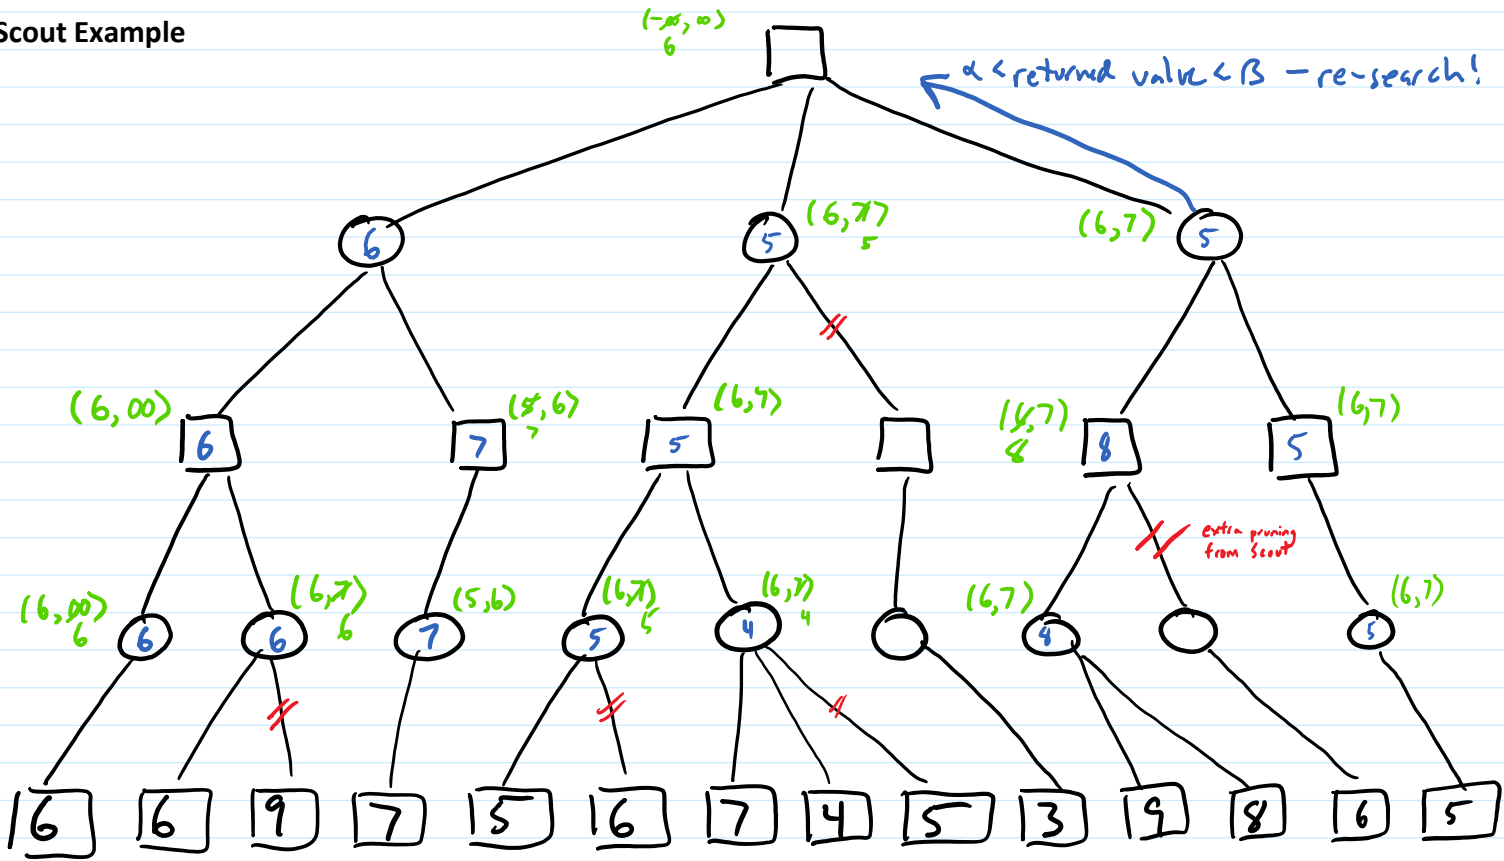

$\alpha < \beta$

null window (assuming integers)

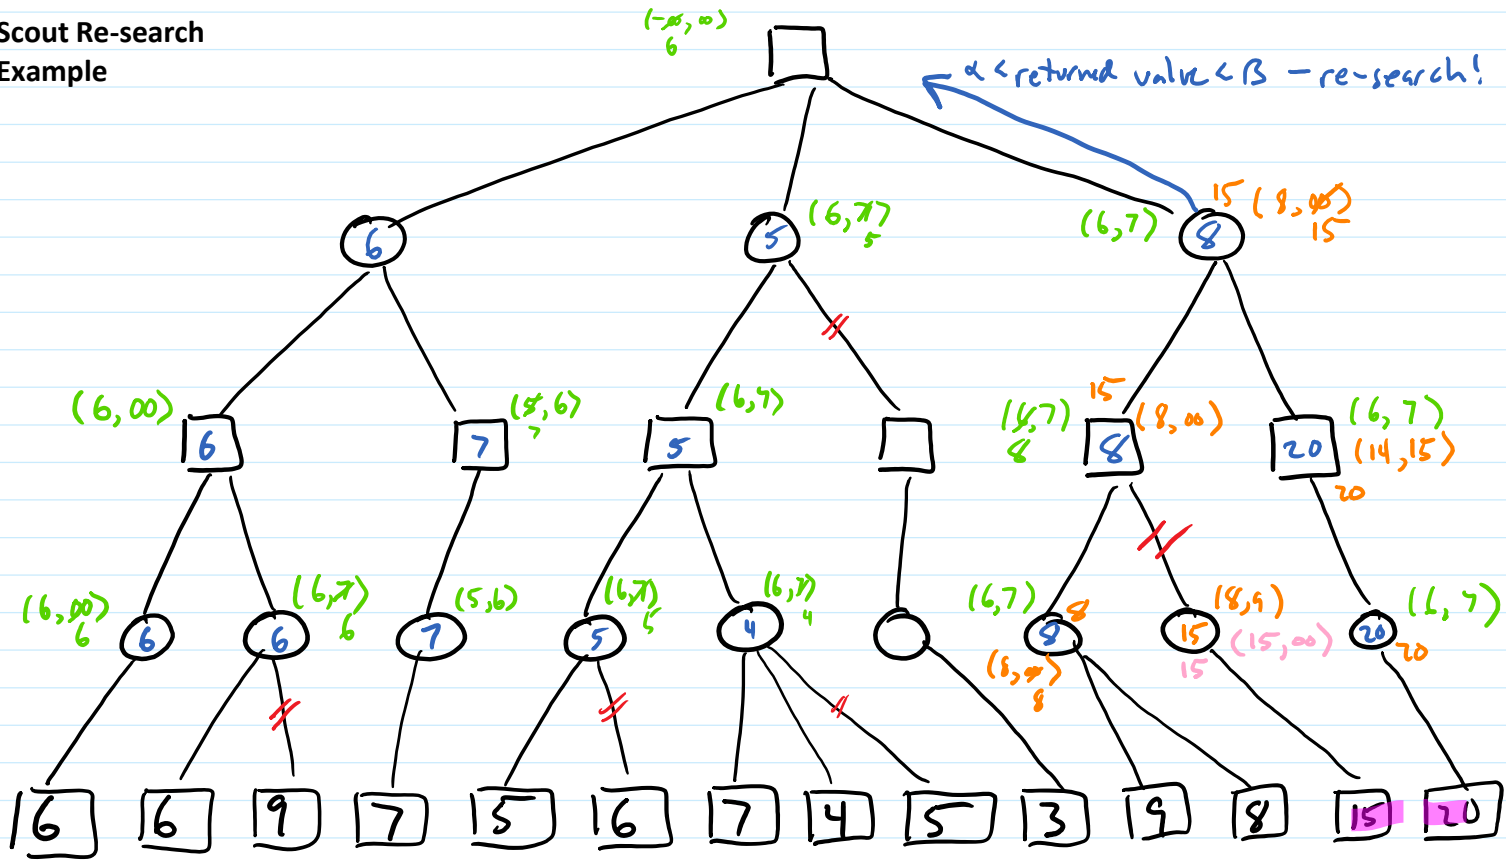

if score $\geq \beta$ then have lower bound on $p' \geq \beta$ so value of $p \geq \beta$ cut off

already know $\text{value}(pos) \geq \text{score}$

Scout Example

Scout Re-search
Example

Transposition Table

Positions may be reachable by multiple sequences of moves

Keep table of values for all positions examined in tree

Keys: positions

Values: (value/bound, move, depth)

lower, upper bounds
= if exact (given h, depth)

if value/bound from shallower search, ignore

Add check at start of A-B

if pos present and searched depth \geq desired depth
if value is exact, return value
else if upperbound $< \alpha$ return val
else if lowerbound and value $\geq \beta$ return val

Save returned values in table

fixed size - replacement policy

deepest
largest
newest
two-level

MTD-f

pos to eval first guess
MTD-f (n, f, d)

assuming integer values

lowerBound $\leftarrow -\infty$

upperBound $\leftarrow \infty$

g $\leftarrow f$

while lowerBound < upperBound

B $\leftarrow \max(\text{lowerBound} + 1, g)$

g $\leftarrow \text{A-B}(n, \text{with TT } \underline{B-1}, \underline{B}, d)$

if g < B upperBound \leftarrow g
else lowerBound \leftarrow g

g-1, g most of the time

return g
